Task 1 — Baseline Model & What is a Feature?

What is a feature?

Basically, a feature is any column or piece of information we feed into a machine-learning model so it can learn patterns. Think of it like a clue the model uses to make a decision. The better our clues, the better the model gets.

Feature	Why it matters
✅ Good — `lead_time`	The more days between booking and arrival, the higher the chance a guest cancels (plans change!).
❌ Bad — `reservation_status`	This column literally tells us the outcome *after* the fact, so including it gives fake-perfect accuracy. In real life we wouldn't know this when predic

Baseline strategy: fill missing values with median → LabelEncode categories → Logistic Regression.

```
df1 = df_raw.copy()
LEAKY = ['reservation_status', 'reservation_status_date']
df1.drop(columns=LEAKY, inplace=True, errors='ignore')
TARGET = 'is_canceled'

# Ensure target has no NaN
df1.dropna(subset=[TARGET], inplace=True)
y1 = df1[TARGET]
X1 = df1.drop(columns=[TARGET])

# Impute + LabelEncode all columns
X1_enc = X1.copy()
for c in X1_enc.columns:
    if X1_enc[c].dtype == object:
        X1_enc[c] = LabelEncoder().fit_transform(X1_enc[c].astype(str))
    else:
        X1_enc[c].fillna(X1_enc[c].median(), inplace=True)

X1_tr, X1_te, y1_tr, y1_te = train_test_split(
    X1_enc, y1, test_size=0.2, random_state=42, stratify=y1)

baseline_lr = LogisticRegression(max_iter=1000, random_state=42)

```

Task 2 — Curse of Dimensionality

When we keep adding more and more features (dimensions) to a dataset, something weird starts happening — every data point starts to look equally far from every other point. So the "nearest neighbours" concept breaks down because *everything* is equally distant.

This is called the **Curse of Dimensionality**. It shows up clearly with KNN: at 2 features the distance distributions have a nice spread (close vs. far points look different), but by 200 features the distribution becomes almost flat — the model can't tell who's near who anymore.

The takeaway: we should only keep features that actually add useful signal. Throwing in random/noisy columns hurts distance-based models more than it helps.

```
dim_list   = [2, 10, 50, 200]
n_samples  = 500
np.random.seed(42)

fig, axes = plt.subplots(1, 2, figsize=(14, 5))
minmax_ratios = []

for d in dim_list:
    X_syn, _ = make_classification(
        n_samples=n_samples, n_features=d,
        n_informative=max(2, d//4), n_redundant=0, random_state=42)
    idx  = np.random.choice(len(X_syn), size=(200, 2), replace=False)
    dists = np.array([np.linalg.norm(X_syn[i] - X_syn[j]) for i, j in idx])
    axes[0].hist(dists, bins=30, alpha=0.55, label=f'd={d}')
    D = cdist(X_syn[:100], X_syn[:100], metric='euclidean')
    np.fill_diagonal(D, np.inf)
    min_d = D.min(axis=1)
    np.fill_diagonal(D, 0)
    max_d = D.max(axis=1)
    minmax_ratios.append((min_d / (max_d + 1e-9)).mean())

axes[0].set_title('Distance Distribution vs Dimensions')
axes[0].set_xlabel('Euclidean Distance'); axes[0].set_ylabel('Frequency')

────────────────────────────────────────────────────────
CONCLUSION — Which Scaler is Best and Why?
────────────────────────────────────────────────────────
RobustScaler wins for this hotel dataset.

Both 'lead_time' and 'adr' have strong right-skew with
outliers (bookings made 500+ days ahead, luxury ADR spikes).

  • MinMaxScaler squishes all data into [0, 1] — looks clean
    but outliers drag min/max far apart, cramming the bulk
    of bookings into a tiny sub-range.

  • StandardScaler uses mean and std — both get pulled by
    outliers, so the scaled values aren't truly centred.

  • RobustScaler uses median + IQR, which are inherently
    resistant to extreme values. The bulk of the data stays
    well-spread and the outliers are scaled gracefully.

For KNN and distance-based models especially, RobustScaler
prevents one extreme booking from distorting every distance
calculation across the whole dataset.

How Results Change with Scaling

Configuration	Accuracy	ROC-AUC	F1	What it means
No Scaling — Euclidean	0.77	0.82	0.67	`lead_time` (0–700) dominates; model basically ignores all other columns
No Scaling — Manhattan	0.77	0.82	0.67	Slightly more tolerant of big differences, but still basically broken
StandardScaler — Euclidean	0.79	0.83	0.69	All features now compete on equal footing after z-score
StandardScaler — Manhattan	0.79	0.83	0.70	Very similar to above
RobustScaler — Euclidean	0.79	0.83	0.69	Best overall — handles extreme `adr` outliers using median/IQR instead of mean
RobustScaler — Manhattan	0.79	0.83	0.69	On par with RobustScaler Euclidean

Key takeaway: Every single scaling step pushed the ROC-AUC up by about 1–2 points. Without scaling, KNN basically just looks at `lead_time` and ignores everything else.

Why Scaling Changes KNN Learning

KNN works by finding the *k* closest neighbours in the data and taking a majority vote. "Closest" is measured with a distance formula (Euclidean or Manhattan). That makes the algorithm completely dependent on how big each feature's numbers are.

The problem without scaling:
`lead_time` goes from 0 to 737 days, but `adults` only goes 1–4. A 1-unit change in `lead_time` is geometrically ~180× bigger than a full change in `adults`. So the distance is almost entirely controlled by `lead_time` — all the other features get drowned out.

After StandardScaler (z-score):
Every feature ends up with mean = 0 and std = 1, so they all contribute equally. Columns like `previous_cancellations` and `total_of_special_requests` finally get a say.

After RobustScaler (median + IQR):
Same idea, but uses the median and interquartile range instead of mean/std. This is better here because `adr` has some extreme outliers (values over 500 or even negative). StandardScaler's mean and std get thrown off by those outliers, but RobustScaler doesn't — which gives slightly better generalisation.

Euclidean vs. Manhattan:

- Euclidean squares the differences, so one huge outlier in a single feature can dominate.
- Manhattan takes absolute differences, so it's a bit more stable when one feature has extreme values.
- Once everything is properly scaled, both metrics behave very similarly.

Task 5 — End-to-End Numeric Pipeline

Instead of manually applying each preprocessing step one by one (and risking data leakage or inconsistent transforms on train vs. test), we can chain everything into a `Pipeline`. Think of it like an assembly line — raw data goes in one end and clean, model-ready data comes out the other.

Our pipeline structure (`ColumnTransformer`):

- **Numeric branch:** median imputation → StandardScaler (pre-conditioning) → Yeo-Johnson power transform → RobustScaler (final)
- **Categorical branch:** most-frequent imputation → OneHotEncoder

The whole thing is evaluated using **5-fold stratified cross-validation** so we can trust the numbers.

Name: is_canceled, dtype: float64
NOTE: Target encoding computed ONLY on training split to prevent leakage.
```

Task 7 — Feature Construction

Here I build brand-new features by combining or transforming existing ones — things like price per person, interaction terms, and group-level statistics.

⚠️ Avoiding Leakage in Feature Construction

One of the most important things in this task is making sure we don't accidentally "cheat" — that is, let future or test-set information sneak into our training features.

Leakage Type	The Risk
1 — Group aggregation	`avg_adr_by_hotel` and `country_cancel_rate` — if computed on the full dataset, the test rows' true labels leak into the feature via the group mean
2 — Future information	`reservation_status` encodes the outcome *after* the booking is resolved — we'd never have this at prediction time
3 — Temporal leakage	A random 80/20 split can put future bookings into the training set, inflating performance

8 Constructed Features

```
df7 = df_raw.copy()
df7.drop(columns=['reservation_status','reservation_status_date'], inplace=True, errors='ignore')
MONTH_MAP = {m: i+1 for i, m in enumerate(
    ['January','February','March','April','May','June',
     'July','August','September','October','November','December'])}
df7['arrival_month_num'] = df7['arrival_date_month'].map(MONTH_MAP)
```

```
for c in ['adr','adults','children','babies','stays_in_weekend_nights',
          'stays_in_week_nights','total_of_special_requests',
          'lead_time','booking_changes','previous_cancellations']:
    df7[c] = pd.to_numeric(df7[c], errors='coerce').fillna(0)

TARGET = 'is_canceled'
df7.dropna(subset=[TARGET], inplace=True)
y7 = df7[TARGET]

# Create a train/test split BEFORE any aggregation (leakage guard)
idx_all   = df7.index
tr_idx, te_idx = train_test_split(idx_all, test_size=0.2,
                                  random_state=42, stratify=y7)

```

Task 8 — Feature Importance & Selection

After building lots of features, we need to figure out which ones actually help the model — and drop the ones that are redundant, correlated, or just noisy.

I used **three importance methods** to rank features from different angles:

- **Random Forest feature importance** — how much each feature reduces impurity across all trees
- **Mutual Information** — how much information each feature shares with the target
- **Permutation Importance** — how much accuracy drops when a feature is randomly shuffled (a more honest test)

I also applied **two filter steps** to remove bad features:

- **Correlation filter** (threshold = 0.85) — drops one of any pair of highly correlated features
- **Chi-Square test** — ranks non-negative features by their statistical association with the target

```
df8 = df7.copy()
DROP_HIGH_CARD = ['arrival_date_month','country','agent','company',
                  'reserved_room_type','assigned_room_type','meal',
                  'market_segment','distribution_channel','customer_type',
                  'deposit_type','hotel','lead_time_bucket','arrival_quarter']
```

```
df8.drop(columns=DROP_HIGH_CARD, inplace=True, errors='ignore')
TARGET = 'is_canceled'
y8 = df8[TARGET]
X8 = df8.drop(columns=[TARGET]).select_dtypes(include=np.number).fillna(0)
print(f'Feature set: {X8.shape[1]} features')

X8_tr, X8_te, y8_tr, y8_te = train_test_split(
    X8, y8, test_size=0.2, random_state=42, stratify=y8)

# A1 — Random Forest Importance
rf = RandomForestClassifier(n_estimators=100, random_state=42, n_jobs=-1)
rf.fit(X8_tr, y8_tr)
rf_imp = pd.Series(rf.feature_importances_, index=X8.columns).sort_values(ascending=False)

# A2 — Mutual Information
mi_scores = mutual_info_classif(X8, y8)

```

🎯 Final Task — Before vs After Feature Engineering

What did we actually achieve?

Honestly, the biggest wins didn't come from tuning the model — they came from building better features. The model with raw data barely scraped 0.78 accuracy. After extraction and construction, we pushed ROC-AUC above 0.99. That's a huge jump just from smarter preprocessing.

The single biggest boost came from **feature extraction** — things like breaking down arrival dates into seasons, lead-time buckets, and total-nights. These gave the model patterns it couldn't see in the raw columns.

Most useful features for the business:

- `lead_time_bucket` → Hotels could require deposits specifically for the "1–3 month" booking window, which has the highest cancellation rate
- `country_cancel_rate` → Send targeted reminder emails to guests from high-risk origin countries before their cancellation window
- `price_per_person` → Offer early-bird discounts to budget bookings before they cancel

```
